Command: poetry init --quiet

This will create a minimal pyproject.toml file without interactive input, which you can edit manually or add dependencies to using poetry add.

After initializing your project with Poetry, you can add the dependencies you listed in your initial question. Run the following command in your project's root directory:

Command: poetry add flask sqlalchemy werkzeug flask_cors chardet loguru

This will add the external libraries (Flask, SQLAlchemy, Werkzeug, Flask-CORS, Chardet, and Loguru) to your project's pyproject.toml file and install them.

Poetry will automatically create and manage a virtual environment for your project. This ensures that your project's dependencies are isolated from other Python projects on your system. You can activate the virtual environment managed by Poetry by running:

poetry run python API.py
